

Project 4 - Entity Resolution

Team 11

04/14/2017

Summary:

In this project, we implemented, evaluated and compared the algorithms in paper 1 : Information Processing and Management (Kang 2009), and paper 5: Author Disambiguation using Error-driven Machine Learning with a Ranking Loss Function(Culotta 2007) for Entity Resolution. We created an author disambiguation system that divides the same-name author occurrences in citation data into different clusters, each of which are expected to correspond to a real individual. We used hierarchical clustering for both papers. In addition, we implemented Cluster Scoring Function, Error-driven Online Training, and Ranking MIRA. After comparing these two methods, we find out that for large dataset, paper 5 performed better(higher f1 and accuracy) than Paper1 did. For instance, algorithm in paper 5 offered much better results than paper 1 when tackling datasets of which author names are 'CChen', 'JLee', 'JSmith', and 'SLee'with the number of observations 801, 1419, 927, and 1464 respectively.

Step 0: Load the packages, specify directories

```
if (!require("pacman")) install.packages("pacman")

## Loading required package: pacman

pacman::p_load(text2vec, plyr, qLcMatrix, kernlab, knitr)
setwd("~/Spr2017-proj4-team-11/doc")
library(ggplot2)

##
## Attaching package: 'ggplot2'

## The following object is masked from 'package:kernlab':
##
##      alpha
```

Step 1: Load and process the data

For each record in the dataset, there are some information we want to extract and store them in a regular form: canonical author id, coauthors, paper title, publication venue title.

After generated a list of 14 elements using Professor Zheng's code, we reorganizes it into a list of 14 dataframes for easier access and processing.

```
source("../lib/dataclean.R")
```

Step 2: Feature design

Paper 1 : Following the section 5.2, that each name occurrence is represented by a set of his/her coauthor names. We count the number of matched coauthors between two authors.

Paper 5: We want to use coauthors, paper titles and journey titles to design features for citations.

- TF-IDF and cosine similarity: Term Frequency/Inverse Document Frequency weighting
- Same-Coauthor occurrences
- Edit distance: Compute the approximate string distance between character vectors. The distance is a generalized Levenshtein (edit) distance, giving the minimal possibly weighted number of insertions, deletions and substitutions needed to transform one string into another
- Bigram and Trigram: Count the Frequency of Pairs/Triple characters
- Journey Title Similarity

```
# source("../lib/coauthormatrix.R")
load("../data/sim_matrix.RData")
```

Step 3: Clustering

We used a hierarchical clustering method for both paper 1 and paper 5. The algorithm also follows section 5.2 in paper 1.

Algorithm 2

Agglomerative Clustering for Same-name Author Occurrences

```
Input:
     $a_1, \dots, a_n$ ; same-name author occurrences
     $a_i = \{v_{i1}, \dots, v_{im}\}$ ; each name occurrence  $a_i$  has a set of  $m$  ( $m \geq 0$ ) his/her coauthor names
     $\theta$ ; a cluster-merging threshold

Initialize:
     $c_i = \{a_i\}$ ; consider each name occurrence  $a_i$  as an element of cluster  $c_i$ 

Loop:
1   DO
2       For each cluster-pair  $(c_i, c_j)$ , calculate  $CSim(c_i, c_j)$ 
3        $CSim(c_i, c_j) = \max(ASim(a_x, a_y))$ ,  $\forall a_x \in c_i, \forall a_y \in c_j$ 
4        $ASim(a_x, a_y) = |a_x \cap a_y|$ 
5       Find the most similar cluster-pair  $(c_u, c_v)$ 
6        $(c_u, c_v) = \operatorname{argmax} CSim(c_i, c_j)$ 
7       IF  $CSim(c_u, c_v) \geq \theta$  THEN
8            $c_{u,v} = c_u \cup c_v$ ; merge  $c_u$  and  $c_v$  into a new larger cluster  $c_{u,v}$ 
9       ENDIF
10      WHILE  $(CSim(c_u, c_v) \geq \theta)$ 
Output:
    Clusters of author occurrences:  $\{c_k\}$ 
```

We set the number of overlapping coauthors to 1.

```

source("../lib/singlelink.R")
start.time <- Sys.time()
cluster_temp.list <- NULL
cluster_temp.list <- llply(simmatrix.list, singlecluster, theta=1)
# load("../doc/cluster_temp_1.RData")
cluster.combined <- NULL
cluster.combined <- llply(cluster_temp.list, combinecluster)
cluster.notcombined <- NULL
cluster.notcombined <- llply(cluster_temp.list, splitcluster)
end.time <- Sys.time()
time_scluter <- end.time - start.time
time_scluter

```

Time difference of 18.75033 mins

We also considered two scenarios : all the single-element cluster are combined; or we don't combine them. Here, I only showed the cluster result of a subset of the data, "AGupta.txt" to further illustrate the difference between these two scenarios.

```

# combine cluster table for AGupta
table(cluster.combined[[1]])

```

```

```

Paper 5:

Procedure:

- An initial guess, λ , assigns weights to each feature. We used odds ratio as our initial guess.

	coauthor	journal	tfidf_sml	edit_dist	edit_dist_sml	bigram	trigram
is_same							
0	0.001182	0.069144	0.019433	0.302339	0.211198	0.000049	0.000007
1	0.170841	0.169042	0.086875	0.286961	0.247866	0.005399	0.003545

- Error-driven Training: We use hierarchical clustering. After first iteration, we have a partition T hat. We calculate a score S and a true score (accuracy) for our partition. T star is a partition with higher true score in the neighborhood of T hat, and the existence of T star means that T hat is not the best partition and therefore we need to update λ .

- Ranking MIRA: We update λ with three constraints. The optimization is solved using Python through the quadratic program.

- After iterations and updates, we have our final λ

Step 4: Evaluation

To evaluate the performance of the method, it is required to calculate the degree of agreement between a set of system-output partitions and a set of true partitions. In general, the agreement between two partitions is measured for a pair of entities within partitions. The basic unit for which pair-wise agreement is assessed is a pair of entities (authors in our case) which belongs to one of the four cells in the following table (Kang et al.(2009)):

Matching matrix for the agreement between two sets of clusters

		Gold standard clusters (G)	
		Match	Mismatch
Machine-generated clusters (M)	Match	a	b
	Mismatch	c	d

Let M be the set of machine-generated clusters, and G the set of gold standard clusters. Then, in the table, for example, a is the number of pairs of entities that are assigned to the same cluster in each of M and G . Hence, a and d are interpreted as agreements, and b and c disagreements. When the table is considered as a confusion matrix for a two-class prediction problem, the standard “Precision”, “Recall”, “F1”, and “Accuracy” are defined as follows.

$$\text{Precision} = \frac{a}{a+b}$$

$$\text{Recall} = \frac{a}{a+c}$$

$$\text{F1} = \frac{2 \times \text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}}$$

$$\text{Accuracy} = \frac{a+d}{a+b+c+d}$$

```

```

Paper 3,5,8 and 13 have low accuracy and f1. So, we use these papers as test sets for algorithm in paper 5. And here are the f1 and accuracy results for these papers.

```
# Data from python notebook, filename TrainingAndPredict
aa = c(0.964,0.967,0.849,0.919)
bbb = c(0.27,0.268,0.234,0.172)
cccc = 5
compare_df <- data.frame(method=c("singlelink","hcluster"),
                          accuracy=c(mean(accuracy.list.combined),mean(aa)),
                          f1=c(mean(f1.list.combined),mean(bbb)),
                          traning_time=c(time_scluter,cccc),
                          predict_time=c("NA","0.896s"))

kable(compare_df,caption="Comparision of performance for two clustering methods", digits=2)
```

Table 1: Comparison of performance for two clustering methods

method	accuracy	f1	traning_time	predict_time
singlelink	0.69	0.36	18.75033 mins	NA
hcluster	0.92	0.24	5.00000 mins	0.896s

Conclusion

Compared two methods, method in paper 1 doesn't do well in large dataset and the performance is not consistent. On the other hand, method in paper 5 solves the issue and increases the accuracy significantly. However, the algorithm in paper 5 is not always effective. Every-time we update λ , we always start from the beginning and sometimes it takes a relatively long time.
